Department of Chemistry, Indian Institute of Technology, Banaras Hindu University, Varanasi 221005, India.

الملخص:
تم تحضير لدينة من نوع قاعدة شيف تحتوي على الأنيلين- فورمالدهيد والبيبيرازين (AFPP) ودراسة استخدامها كمانع لتآكل الفولاذ الطري في وسط حمض الكلوريك المولاري عن طريق قياس فقدان الوزن وطريقة مطيافية الممانعة الكهروكيميائية وتقنية قياس استقطابية فرق الجهد الديناميكي. أوضحت نتائج التجربة أن لدينة من نوع AFPP هي مانع فعال لـ تآكل الفولاذ الطري في وسط حمض الهيدروكلوريك المولاري حيث أعطت كفاءة منع بنسبة 89%. ودللت قياسات استقطابية فرق الجهد الديناميكي على أن AFPP هو نوع من الموانع المختلطة التي يغلب عليها المنحني الكاثودي. وقد وجد أن إمتصاص (إمتزاز) مانع التآكل هذا على سطح الفولاذ الطري يتم وفقاً لقانون انجمامور للإمتصاص متساوي الحرارة. كذلك قد تم تعين طاقة التنشيط ($E_a$) و طاقة الإمتصاص القياسية ($\Delta G^\circ_{ads}$) و طاقة المحتوى الحراري ($\Delta H^\circ$) وانتروبيا التنشيط ($\Delta S^\circ$) لعملية التآكل.

Received 29 August 2013; revised 4 April 2014; accepted 27 April 2014
Available online 20 June 2014

Abstract Polymeric Schiff base containing aniline, formaldehyde and piperazine (AFPP) was synthesized and investigated as corrosion inhibitor for mild steel in 1 M HCl by weight loss measurements, electrochemical impedance spectroscopy (EIS) and potentiodynamic polarization techniques. Experimental results showed that AFPP is an effective inhibitor for mild steel in 1 M HCl and exhibited 98% inhibition efficiency. Potentiodynamic polarization studies showed that AFPP is a mixed-type inhibitor predominantly cathodic type. The adsorption of inhibitor on the mild steel surface followed Langmuir adsorption isotherm. Activation energy (Ea), standard energy of adsorption (DG_ads), enthalpy of activation (DH*), and entropy of activation (DS*) of corrosion process were calculated and discussed.

1. Introduction

The corrosion inhibition of mild steel has tremendous technological importance due to its increased industrial applications (Ali et al., 2003). Corrosion is the serious problem that mankind is facing (Ahmad and MacDiarmd, 1996).

Acid has wide applications in industry such as in pickling, cleaning, decaling etc. To prevent the corrosion of the metal, inhibitors are extensively used. The selection of an inhibitor mainly depends upon its efficiency, economic feasibility and side effects on the environment.

The use of polymers as corrosion inhibitors has drawn considerable attention due to their inherent stability, cost effectiveness and better inhibition efficiency at a very low concentration (Umoren et al., 2008). Both natural and synthetic polymers have been used as corrosion inhibitors (Shukla and Quraishi, 2012). These polymers have high molecular weight and bulky structure due to this they can cover more area on the metal surface, which leads to high inhibition efficiency.

In continuation of our work on corrosion inhibition by polymers (El-Etre, 1998; Shukla et al., 2008; Quraishi and Shukla, 2009), we have reported the corrosion inhibition effect of polymer derived from aniline, formaldehyde and piperazine (AFPP) (Parveen et al., 2008) which increases the corrosion inhibition property at low concentration (100 mg L⁻¹) with inhibition efficiency of 98%.

In the present work we have studied the inhibitive effect of polymer derived from aniline, formaldehyde and piperazine (AFPP) on mild steel in 1 M hydrochloric acid (HCl) by using...
weight loss, electrochemical impedance spectroscopy (EIS), and potentiodynamic polarization techniques. According to literature survey, no work has been done on this compound as corrosion inhibitor.

2. Experimental

2.1. Materials and chemicals

The inhibitor under investigation has been synthesized elsewhere (Parveen et al., 2008). Its scheme of synthesis is shown in Fig. 1.

The corrosion test was performed on the mild steel strips containing (in wt.%) C: 0.076, P: 0.012, Si: 0.026, Mn: 0.192, Cr: 0.050, Cu: 0.135, Al: 0.023, Ni: 0.050 and remaining Fe. Mild steel strips used for weight loss measurement have dimension 2.5 cm × 2.0 cm × 0.025 cm. For electrochemical measurements, 7.5 cm long stem of mild steel strips with exposed surface area of 1.0 cm² (rest being coated with commercially available lacquer) was used. The test solution, 1 M HCl was prepared by dilution of analytical grade HCl with distilled water. The inhibitor concentration ranges from 25 to 100 mg L⁻¹.

2.2. Methods

2.2.1. Weight loss measurements

The weight loss measurements of mild steel strips of size 2.5 cm × 2.0 cm × 0.025 cm were used in 1 M HCl without and with addition of different concentrations of inhibitor for 3 h at 308 K temperature without stirring. Following equations were used for the determination of inhibition efficiency (η) and surface coverage (θ):

\[
\eta = \frac{C_{R} - C_{R(i)}}{C_{R}} \times 100
\]

\[
\theta = \frac{C_{R} - C_{R(i)}}{C_{R}}
\]

where \(C_{R}\) and \(C_{R(i)}\) are the values of the corrosion rates (mg cm⁻² h⁻¹) of mild steel in the absence and presence of inhibitor, respectively.

2.2.2. Electrochemical measurements

All electrochemical experiments were performed in Gamry electrochemical cell with three electrode cell, consisting of a mild steel rod of 1 cm² as working electrode, a platinum foil as counter electrode and standard calomel electrode (SCE) as a reference electrode, connected to Gamry Instrument Potentiostat/Galvanostat with a Gamry framework system based on ESA 400. Gamry applications include EIS 300 for EIS measurements, DC 105 software for corrosion and Echem Analyst (version 5.50) software package for data fitting. All potentials were measured versus SCE. The electrolyte used was 1 M HCl maintained at 308 K.

2.2.2.1. Electrochemical impedance spectroscopy (EIS). EIS measurements were carried out with Gamry Instrument Potentiostat/Galvanostat, which consists of a unit with a potentiostat and an acquisition system. The principle of this analytical technique consists of superposing a slight sinusoidal voltage \(ΔE\) sin \(at\) (10 mV peak to peak) from high to low frequency \((10^3–10^2)\) Hz to the potential applied to the sample.

2.2.2.2. Potentiodynamic polarization. Potentiodynamic polarization curves were obtained by changing the electrode potential automatically from −250 to +250 mV versus \(E_{OC}\) at a scan rate of 1 mV s⁻¹. All experiments were measured after immersion for 30 min in 1 M HCl in the absence and presence of inhibitor.

3. Experimental results and discussion

3.1. Weight loss measurements

3.1.1. Effect of inhibitor concentration

Effect of inhibitor (AFPP) concentration on the corrosion of mild steel in 1 M HCl was studied by weight loss measurement at 308 K and the results are given in Table 1.

The data in Table 1 reveal that as the concentration of AFPP increases inhibition efficiency increases (Karthikaiselvi and Subhashini, 2014) and corrosion rate decreases. This behavior can be attributed to the increase in surface area covered by the adsorbed molecules on the mild steel surface with an increase in the concentration of AFPP. The maximum efficiency of 98% was achieved at the concentration of 100 mg L⁻¹.

3.1.2. Effect of temperature

The inhibition efficiency in 1 M HCl at optimum concentration (100 mg L⁻¹) of AFPP at temperature ranging from 308 to 338 K was done and result obtained is given in Table 2.

From Table 2, it was found that the inhibition efficiencies decrease and corrosion rate increases with increasing temperature. This phenomenon can be explained with the desorption of adsorbed inhibitor molecules from the mild steel surface. Due to this greater surface area of mild steel comes in contact with corrosive environment which results in an increase in the corrosion rate (Fouda and Ellithy, 2009). The activation parameters were calculated by using Arrhenius equation (Tao et al., 2009).

\[
C_R = A \exp \left( -\frac{E_a}{RT} \right) \tag{3}
\]

where \(E_a\) is the activation energy, \(R\) is the gas constant, \(A\) is the pre-exponential factor.

Arrhenius plot for the corrosion rate of mild steel is given in Fig. 2a. Linear regression between \(\log(C_R)\) and \(1/T\) is used to calculate the value of activation energy \(E_a\) for mild steel in 1 M HCl in the absence and presence of inhibitor, results are listed in Table 3.

From Table 3, it was found that the value of \(E_a\) is higher for inhibited solution than that for uninhibited. This higher value of \(E_a\) is obtained due to adsorbed inhibitor molecules which create physical barrier for charge and mass transfer (Martinez and Stern, 2002).

Enthalpy and entropy of activation can be calculated by using Arrhenius equation (Tao et al., 2009):

\[
C_R = \frac{RT}{Nh} \exp \left( -\frac{\Delta S^*}{R} \right) \exp \left( -\frac{\Delta H^*}{RT} \right) \tag{4}
\]

where \(h\) is Plank’s constant, \(N\) is Avogadro’s number, \(\Delta S^*\) is the entropy of activation and \(\Delta H^*\) is the enthalpy of activation.

A plot of \(\log(C_R/T)\) against \(1/T\) gives straight lines with slope values of \((\Delta H^*/2.303R)\) and an intercept of \([\log(R/Nh)] + (\Delta S^*/2.303R)\) as in Fig. 2a, from which the values of \(\Delta H^*\) and \(\Delta S^*\) were calculated and given in Table 3. The positive value of \(\Delta H^*\) and \(\Delta S^*\) gives an evidence of endothermic nature of dissolution of mild steel, which suggests the slower dissolution of mild steel in the presence of inhibitor (Tao et al., 2009). As from Table 3, the sign of \(\Delta S^*\) is negative in blank and positive in the presence of inhibitor. The adsorption of organic inhibitor molecules on the mild steel surface can be regarded as a quasi-substitution process between the organic compound in the aqueous phase \([\text{Org}_{(sol)}]\) and water molecule on electrode (mild steel) surface \([\text{H}_2\text{O}_{(ads)}]\) (Sahin et al., 2002) (Fig. 2b).

\[
\text{Org}_{(sol)} + x\text{H}_2\text{O}_{(ads)} \leftrightarrow \text{Org}_{(ads)} + x\text{H}_2\text{O}_{(sol)}
\]

where \(x\) is the size ratio, that is, the number of water molecules replaced by one organic inhibitor. In this situation, the adsorption of inhibitor is accompanied by desorption of water molecules from the surface. Therefore, the gain in entropy is attributed to the increase in solvent entropy and to more positive water desorption enthalpy (Branzoi et al., 2000; Ateya et al., 1984). The positive value of \(\Delta S^*\) also means that disordering increases on going from reactants to the metal/solution interface (Banerjee and Malhotra, 1992), which is the driving force for the adsorption of inhibitor onto the mild steel surface (Li et al., 2008).

3.1.3. Adsorption considerations

In order to gain more information about the type of interaction between the inhibitor molecules and the mild steel surface,
different adsorption isotherms were tested. The Langmuir isotherm, Eq. (5), was found to fit well with the experimental data obtained from the investigated compound (Xometi et al., 2008).

\[ K_{\text{ads}} C_{\text{inh}} = \frac{\bar{\theta}}{1 - \bar{\theta}} \]  

(5)

where \( \bar{\theta} \) is the surface coverage, \( C_{\text{inh}} \) is the inhibitor concentration (mg L\(^{-1}\)); \( K_{\text{ads}} \) is the equilibrium constant of adsorption process. The plot of \( C_{\text{inh}}/\bar{\theta} \) vs inhibitor concentration \( (C_{\text{inh}}) \) was evaluated and given in Fig. 2c.

3.2. Electrochemical Measurements

3.2.1. AC technique: Electrochemical impedance spectroscopy

Nyquist plots of the inhibitor in 1 M HCl solution in the absence and presence of different concentrations of AFPP are given in Fig. 3a. The impedance spectra show a single semicircle and the diameter of semicircle increases with increasing inhibitor concentration. The impedance spectra consist of one capacitive loop from high frequency to low frequency, the high frequency capacitive loop was attributed to charge transfer of the corrosion process (Paskossy, 1994). From the figure it is noticed that the impedance spectra have a “depressed” semicircle at the center under the real axis, this phenomenon often refers to the frequency dispersion of interfacial impedance which has been attributed to the roughness; inhomogeneities of the solid surfaces and adsorption of inhibitor (Growcock and Jasinski, 1989; Bustamante et al., 2009).

The equivalent circuit model used to fit the experimental results is shown in Fig. 3b.

It consists of solution resistance \( (R_s) \), charge transfer resistance \( (R_{ct}) \) and constant phase element (CPE). The admittance, \( Y_{\text{CPE}} \), and impedance, \( Z_{\text{CPE}} \), are expressed as (Khaleed, 2010).

\[ Y_{\text{CPE}} = Y_0(j\omega)^n \]

(6)

\[ Z_{\text{CPE}} = \frac{1}{Y_0(j\omega)^n} \]

(7)

where \( Y_0 \) is the amplitude comparable to a capacitance, \( j \) is the square root of \(-1\), \( \omega \) is angular frequency \( (\omega = 2\pi f_{\text{max}}) \), \( n \) is the phase shift, which can be used as a gauge of the heterogeneity or roughness of the mild steel surface. The CPE can be expressed by the values of \( n \) if resistance \( (n = 0, Y_0 = R) \), capacitance \( (n = 1, Y_0 = C) \), inductance \( (n = -1, Y_0 = L) \) and Warburg impedance \( (n = 0.5, Y_0 = W) \) (Khaleed and Amin, 2009).

The double layer capacitance \( (C_{dl}) \) values can be calculated from CPE parameter values \( Y \) and \( n \) using the following equation (Zhang et al., 2009).

\[ C_{dl} = \frac{Y_0\omega^{-1}}{\sin(n(\pi/2))} \]  

(8)

The inhibition efficiency \( (\eta\%) \) using \( R_{ct} \) values was calculated from the equation (Quraishi et al., 2012).

\[ \eta\% = \left( 1 - \frac{R_{ct}}{R_{ct(i)}} \right) \times 100 \]  

(9)

where \( R_{ct(i)} \) and \( R_{ct} \) are the charge transfer resistance in the presence and absence of optimum concentration of AFPP.

According to the expression of the double layer capacitance presented in the Helmholz model:

\[ C_{dl} = \frac{\varepsilon_0 S}{\varepsilon} \]

(10)

where \( \varepsilon_0 \) is the permittivity of free space \( (8.854 \times 10^{-12} \text{ F m}^{-1}) \) and \( \varepsilon \) is the local dielectric constant of medium, \( S \) is the surface area of the electrode. Eq. (10) suggests that \( C_{dl} \) is inversely proportional to \( d \).

It can be seen from Table 4 that the value of \( R_{ct} \) increases as the inhibitor concentration increases. The value of \( R_{ct} \) ranges from 59.7 to 618.5 \( \Omega \text{ cm}^2 \) and \( C_{dl} \) from 29.4 to 15.3 \( \mu\text{F cm}^{-2} \). The large \( R_{ct} \) is associated with a slower corroding system, due to a decrease in the active surface necessary for the corro-
In the beginning of the immersion the gradual approach of $-S$ and $-\alpha^\theta$ to the ideal capacitive values may be related to slowing down the rate of dissolution with time. For the same reason, in the presence of inhibitor (Table 5) there is the faster attaining of steady state of $-S$ and $-\alpha^\theta$ and their higher values correspond to the catalytic action of the inhibitor in the mild steel dissolution process (Maranhao et al., 2006). The Bode phase angle plots show single maximum (one time constant) at intermediate frequencies, which is slightly broadened in the presence of inhibitor which may be due to the formation of a protective layer (Solmaz et al., 2008).

### 3.2.2. DC techniques: Tafel and linear polarizations

Polarization curves for mild steel/inhibitor interface in 1 M HCl at 308 K in the absence and presence of different concentrations of AFPP are shown in Fig. 4.

The corrosion inhibition efficiency was calculated by using the following equation (McCafferty and Hackerman, 1972):

$$\eta = \frac{1}{1 + K} \times 100$$

Where $K$ is the inhibitor constant.

**Figure 3c** Bode impedance plots for mild steel in 1 M HCl in the absence and presence of different concentrations of AFPP at 308 K.

**Figure 4** Potentiodynamic polarization curves for mild steel in 1 M HCl in the absence and presence of different concentrations of AFPP at 308 K.
since the deviation in $E_{\text{corr}}$ is less than 85 mV, it could be recognized as mixed type of inhibition. The positive sign of $\beta_a$ demonstrated that the inhibitor under investigation is mixed-type (Bammou et al., 2014) whereas if the deviation in $E_{\text{corr}}$ is greater than 85 mV in inhibited system with respect to uninhibited, the inhibitor could be recognized as cathodic or anodic inhibited, the inhibitor might be protonated in the acid solution as follows:

$$\text{AFPP} + x\text{H}^+ \leftrightarrow [\text{AFPPH}]^{x+}$$

2. The protonated inhibitor may adsorb through electrostatic interactions between the positively charged molecules and the negatively charged metal surface, i.e. there may be a synergism between Cl$^-$ and protonated inhibitor.

3. This physically adsorbed protonated inhibitor molecules undergo competition with H$^+$ ions for electrons on the mild steel surface. Cationic form of inhibitor returns to its neutral state after release of H$_2$ gas and heteroatoms with free lone pair electrons promote chemical adsorption.

4. Also the electron from d-orbital of Fe might be transferred to vacant $\pi^*$ (antibonding) orbital of inhibitor molecules (reterodonation) and which strengthen adsorption.

5. Protonated inhibitor molecules may combine with freshly generated Fe$^{2+}$ ions on the mild steel surface forming metal inhibitor complexes which is as follows:

$$\text{Fe} \leftrightarrow \text{Fe}^{2+} + 2e^-$$

$$\text{AFPP} + \text{Fe}^{2+} \rightarrow [\text{AFPP} - \text{Fe}]^{2+}$$

$$[\text{AFPP}]^{x+} + \text{Fe}^{2+} \rightarrow [\text{AFPP}_x - \text{Fe}]^{(2+x)+}$$

4. Conclusion

The studied inhibitor shows excellent inhibition properties for corrosion of mild steel in 1 M HCl and its inhibition efficiency increases with increasing the concentration. The results obtained from weight loss measurements, polarization curves and electrochemical impedance study (EIS) are in reasonable agreement. The adsorption of the inhibitor obeys Langmuir adsorption isotherm. The result of polarization measurement demonstrated that the inhibitor under investigation is mixed-type but predominantly cathodic. The positive sign of $\Delta H^\circ$ indicates that the adsorption process is endothermic.
