Abstract In this paper, a mathematical model of nitric oxide removal using biotrickling filter (BTF) packed with uniform ceramic particles under thermophilic condition is discussed. The model proposed here is based on the mass transfer in gas-biofilm interface and chemical oxidation in the gas phase. Analytical expressions pertaining to the nitric oxide (NO) concentration in the gas and bio-film phase have been derived using the Adomian decomposition method (ADM) for all possible values of parameters. Furthermore, in this work the numerical simulation of the problem is also reported using Matlab program to investigate the dynamics of the system. Graphical results are presented and discussed quantitatively to illustrate the solution. Good agreement between the solutions is presented in this paper and numerical data are obtained.

1. Introduction

Rapid increases in the emission of nitrogen oxides (NOx) can adversely affect human health, damage crops, and are implicated in the formation of acid rain (Van Langenhove et al., 1986). Nitrous oxide, a chemical compound with the formula N2O is one of the NOx components which are known as laughing gas in common. It is an oxide of nitrogen. At room temperature, it is a colourless, non-flammable gas, with a slightly sweet odour and taste. Nitrous oxide is a long-lived greenhouse gas, with a direct global warming potential 298 times higher than that of carbon dioxide (Solomon et al., 2007). Therefore, even low amounts of N2O emission are unwanted. Nitrous oxide gives rise to nitric oxide (NO) on reaction with oxygen atoms and this NO in turn reacts with ozone. Nitric oxide which is the major component of nitrogen oxide reacts with moisture in the air to form nitrous acid which is a major constituent of acid rain.

In order to control the emission of volatile organic compounds (VOC) like nitrous oxide, nitric oxide, toluene etc. from industries, biofilters are being used nowadays instead of the chemical complex absorption method (Islam and Alam, 2006; Vafajoo et al., 2012). Biofilters offer two major
advantages to an energy-starved country like India. Their power consumption is very low (1.8–2.5 Kwh/1000 m³) compared with other technologies. Secondly, their capital operating costs are very low which can be an added boon to our industry, which opt for high economic pollution control technologies (James and Natalve, 1996). Biofiltration is a complex process with many physical, chemical, and biological phenomena (Devinnny et al., 2002). In biofiltration the contaminated air is passed through a packed bed where biodegradable gases or volatile compounds are absorbed into the biofilm (Baquerizo et al., 2005).

Biofiltration has become one of the leading technologies for controlling VOC emissions (Zarook and Shaikh, 1997; Cox and Deshusses, 1998). There are three conventional types of biofilter: biofilter, trickling biofilter and bioscrubber. Biotrickling filters have been shown in several instances to be superior to biofilters when accurate control of the environmental conditions or higher pollutant elimination rates are required (Baltzis et al., 2001). Moreover, biotrickling filters packed with better structural strength can be built taller than biofilters (Cox et al., 2001). A liquid stream trickles through the porous packed bed and provides nutrients without carbon to the micro-organisms. The micro-organism in the biofilm degrades the biodegradable pollutants in waste gas while it passes through the packed bed and diffuses through the attached biofilm. Biotrickling filters are relatively new and are still regarded as an emerging technology for air pollution control (Liao et al., 2008). Biotrickling filters require low maintenance (Deshusses Marc et al., 2004). Biotrickling filters are increasingly used in industrial applications.

NO removal by applying some thermophilic microorganisms in various temperatures was studied experimentally by Flanagan and Lee (Flanagan et al., 2002; Lee et al., 2001). Besides, theoretical modelling studies regarding NO removal in BTF reactor are very limited due to the non linear character of mass balance equations over the biofilm phase. Caceres, Song and Zarook analysed the BTF modelling on removal of volatile organic compounds (Caceres et al., 2012; Song and Kinney, 2002; Zarook and Shaikh, 1997). Liang et al. (2012) developed a mathematical model for nitric oxide removal in a biotrickling filter under thermophilic conditions. Matlab software package was employed to acquire the numerical solution of the model. However to the best of our knowledge, no rigorous analytical expressions of concentration of nitric oxide in the gas phase and in the biofilm phase have been reported (Liang et al., 2012). The purpose of this communication is to derive the approximate analytical expressions for the nitric oxide concentration in both the phases using the Adomian decomposition method.

2. Mathematical modelling

The experimental setup for the BTF reactor is given in Fig. 1. The BTF was constructed with cylindrical plexiglass. The height and diameter of the reactor were 50 and 8 cm, respectively. The packing space was at the height from 10 to 40 cm calculated from the bottom of the BTF. The outer layer of the reactor was shielded with a heat tape which is covered with a layer of fibreglass insulator. The reactor temperature was maintained at 50 ± 1°C. The experiment was conducted in two experimental phases. In the first phase, the characteristics of *Chelatococcus daeguensis* in anaerobic environment in the presence of nitrate were found out. In the second phase, the potentiality of immobilization material in the biofilter which could adsorb NO₂ gas effectively as well as possess good bacterial immobilization capacity was identified (Islam and Alam, 2006). Let us consider the mass balance equations for

![Figure 1](image-url)
micro-volume units in the gas phase and the biofilm phase respectively on the basis of operation conditions in Liang et al. (2012) as follows:

Mass balance equation over the gas phase:

\[
U_g \frac{dC_g}{dz} = a_f D_e \frac{dC_l}{dx} |_{x=0} - 2k_g C_g^2 \eta_f
\]

where \( U_g \) is the superficial gas velocity; \( C_g \) is the NO concentration in the gas phase and \( C_l \) is the NO concentration in the biofilm phase; \( a_f \) is the specific surface area of biofilm; \( D_e \) is the effective diffusion coefficient in the biofilm; \( k_g \) is the reaction rate constant; \( \eta_f \) is porosity ratio of biofilm covered packing materials; \( -D_e \frac{dC_l}{dx} \bigg|_{x=0} \) is the flux across the gas biofilm interface; \( z \) is the height value which is calculated from the base of the packing materials; \( x \) is the coordinate axis which is calculated from the surface of the biofilm. The equation (Eq. (1)) must be solved to the boundary condition

\[
C_g = C_{g,0} \quad \text{at} \quad z = 0,
\]

Mass balance equation over the biofilm phase is

\[
D_i \frac{d^2 C_i}{dx^2} = \frac{\mu_m}{Y} - \frac{C_i}{K_i + C_i} X_V
\]

where \( X_V \) is the microbial density of the biofilm; \( K_i \) is the Monod half saturation constant; \( \mu_m \) is the maximum specific growth rate of biomass; \( Y \) is the yield coefficient of micro-organisms; \( \mu_m/Y \) gives the maximum specific substrate utilization rate. Boundary conditions for Eq. (3), are given by

\[
C_i = C_{i,0}/H \quad \text{at} \quad x = 0
\]

\[
\frac{dC_i}{dx} = 0 \quad \text{at} \quad x = L_f
\]

where \( H \) is Henry constant at 50°C and \( L_f \) is the biofilm thickness. The NO concentrations in both the gas and biofilm phase were analysed experimentally by a flue gas analyser (TESTO 350Pro, Germany) at 10 h intervals (Liang et al., 2012).

2.1. Dimensionless form

The non-linear differential Eqs. (1) and (3) are made dimensionless by defining the following parameters:

\[
C_i = \frac{C_i}{C_{i,0}}, \quad \bar{x} = \frac{x}{L_f}, \quad \bar{z} = \frac{z}{L_f}, \quad \alpha = \frac{\alpha D_i}{\mu_m}, \quad \beta = \frac{C_{i,0}H}{K_i},
\]

\[
C_g = \frac{C_g}{C_{g,0}}, \quad \bar{C}_g = \frac{\bar{C}_g}{C_{g,0}}, \quad \bar{z} = \frac{z}{L_f}, \quad \gamma = \frac{\alpha D_i}{\mu_m}, \quad \eta = \frac{\eta_f L_f}{C_{g,0}}
\]

Using the above dimensionless variables, Eqs. (1) and (3) reduce to the following dimensionless form:

\[
\frac{d\bar{C}_g}{d\bar{z}} = \gamma C_g \frac{d\bar{C}_l}{d\bar{x}} |_{x=0} - 2\eta \bar{C}_g^2
\]
The corresponding boundary conditions for the above Eqs. (7) and (8) can be expressed as

\[ C_g = 1 \quad \text{at} \quad \bar{z} = 0, \]  
\[ \tilde{C}_i = 1 \quad \text{at} \quad \bar{x} = 0 \]  
\[ \frac{d\tilde{C}_i}{dx} = 0 \quad \text{at} \quad \bar{x} = 1 \]  

3. Analytical expressions of concentration of NO in gas and biofilm phase using Adomian decomposition method

In the recent years, much attention is devoted to the application of the Adomian decomposition method to the solution of various scientific models (Adomian, 1984; Mohamed, 2010; Omar Jaradat, 2008; Siddiqui et al., 2010). The ADM yields an analytical solution in terms of a rapidly convergent infinite power series with easily computable terms and without linearization, perturbation, transformation or discrimination. In this paper, the Adomian decomposition method (see Appendix A) is used to solve non-linear differential equation (Muthukaruppan et al., 2012). The analytical expressions for the concentration of NO in the gas phase \( \tilde{C}_g \), and in the biofilm phase \( \tilde{C}_i \) (see Appendix B) are obtained as follows:

\[ C_g(\bar{z}) = \gamma m e^{m\bar{z}}[\gamma m - 2\eta + 2\eta e^{m\bar{z}}]^{-1} \]  
\[ \tilde{C}_i(\bar{x}) = 1 + \frac{x^2\bar{x}(\bar{x} - 2)}{2(1 + \beta)} + \frac{x^2\bar{x}^2(\bar{x} - 4) + 8)}{24(1 + \beta)^3} \]  

where

\[ m = \frac{x^4}{3(1 + \beta)^4} - \frac{x^2}{(1 + \beta)} \]  

4. Removal ratio of NO

The percentage of the NO removal ratio (NO removal efficiency \( NO_{R} \)) is (Takao Namihira et al., 2000)

\[ NO_{R} = \frac{NO_i - NO_f}{NO_i} \times 100 \]  

where \( NO_i \) and \( NO_f \) are the initial (before treatment) and the final (after treatment) concentrations of NO in the gas phase, respectively. In the present work, \( NO_i = 1 \) and \( NO_f = C_g \).

5. Numerical simulation

In order to investigate the accuracy of the ADM solution with a finite number of terms, the system of differential equations was solved numerically. To show the efficiency of the present method, our results are compared with numerical results graphically. The function pdepe (Finite element method) which is a function of solving initial-boundary value problems for parabolic-elliptic PDEs in 1-D is used to solve Eq. (7) numerically. And Eq. (8) is solved numerically using the Matlab function ode45 (Range–Kutta method) which is a function of solving the initial-boundary value problems in Matlab software (MATLAB 2000, Skeel and Berzins, 1990).
The analytical solutions of NO concentration in the gas phase and the biofilm phase are compared with simulation results in Figs. 1–6 A satisfactory agreement is noted.

6. Results and discussion

Eqs. (12) and (13) represent the simple analytical expressions pertaining to the NO concentration in the gas phase and the biofilm phase respectively. The main variables of interest in this study are the concentration of NO in the gas phase \( C_g \) and the biofilm phase \( C_l \) respectively. The concentration of nitric oxide in the gas phase depends on the following four factors \( c, g, a \) and \( b \). The parameter \( c \) depends upon specific surface area of the biofilm \( a_f \), effective diffusion coefficient \( D_e \), Henry constant \( H \) and superficial gas velocity \( U_g \). The parameter \( a \) and \( g \) depends upon the biofilm thickness \( L_f \). And the factor \( b \) depend on the inlet NO concentration.

Fig. 2(a) shows the dimensionless concentration profile of NO in the gas phase versus dimensionless height \( \bar{z} \) for various values of \( a \). The variation in the dimensionless variable \( a \) can be achieved by varying either the thickness or the microbial density of the biofilm. As \( a \) increases, the concentration of NO increases for \( \bar{z} \leq 5 \). It indicated that the concentration of NO depends upon the thickness of the biofilm. In Fig. 2(b), the influence of \( \beta \) over NO concentration in the gas phase versus height \( \bar{z} \) was analysed. For some fixed values of the parameters the concentration increases when \( \beta \) decreases. From this figure, it is also evident that the concentration is inversely proportional to \( \beta \). From Fig. 2(c) it is observed that the concentration of NO increased rapidly since \( \bar{z} < 15 \) and reaches the maximum at \( \bar{z} = 15 \) and then remains approximately constant. Sharp increases are due to the inlet nitrogen concentration \( C_{g,0} \). When \( \eta \) increases the concentration decreases. From this figure, it is deducted that, for minimum values of \( \eta \) the concentration of NO increases. Fig. 2(d) represents the concentration of NO for various values of \( c \). The variation in \( c \) can be accomplished by changing either the diffusion coefficient in the biofilm, or the superficial gas velocity. From this figure, it is confirmed that the concentration increases when \( c \) (specific surface area of the biofilm) increases with respect to the height \( \bar{z} \).

In Fig. 3, the concentration of NO in the gas phase \( C_g \) versus height \( \bar{z} \) for various values of parameters \( \gamma, \eta \) and \( m \) is plotted. The concentration of \( C_g \) increases with the increase of \( \gamma, \eta \) and \( m \). It reaches the steady state value when \( \bar{z} \geq 1 \) for all values of \( \gamma, \eta \) and \( m \). For \( m < 1 \), the concentration decreases for various values of \( \gamma \) and \( \eta \). And for \( m \geq 1 \), the concentration decreases.

Figure 4  Dimensionless NO concentration in the biofilm phase (\( C_l \)) versus dimensionless coordinate \( \bar{x} \) for various values of \( \beta \) and for some fixed values of the parameter \( \alpha^2 \). The key to the graph: solid line represents the Eq. (13) and dotted line represents the numerical simulation.
Figure 5  Dimensionless NO concentration in the biofilm phase ($C_1$) versus dimensionless coordinate $\tilde{x}$ for various values of $\alpha^2$ and for some fixed values of the parameter $\beta$. The key to the graph: solid line represents the Eq. (13) and dotted line represents the numerical simulation.

Figure 6  NO Removal ratio $NO_R$ versus dimensionless height $\tilde{z}$ for various values of $\beta$ and $\eta$ for some fixed values of the other parameters. The graph is plotted using Eq. (15).
Fig. 4 and 5 exhibit the concentration of NO in the biofilm phase \( C_1 \) for different values of \( x^2 \) and \( \beta \). From Fig. 4(a)–(c), it is inferred that the concentration of NO increases when \( \beta \) increases for some fixed values of \( x^2 \). For large values of \( \beta \), the concentration remains constant. In Fig. 5(a)–(c), the concentration of NO in the biofilm phase for various values of \( x^2 \) and for some fixed values of \( \beta \) is presented. From this figure, we conclude that the concentration of NO increases when thickness of the film decreases.

Fig. 6 illustrates the removal ratio of NO (NO removal efficiency) in the gas phase. From Fig. 6(a) and (b), it is evident that the removal ratio increases when \( \beta \) (half saturation constant increases) decreases and \( \eta \) (biofilm thickness) increases. This shows that NO removal efficiency is inversely proportional to the biofilm thickness. Fig. 7 depicts that the difference between the experimental and analytical profiles of NO removal efficiency versus the coordinate axis \( x \). Our obtained analytical results are verified.

Fig. 8 shows the profile of NO concentration and NO removal efficiency versus coordinate axis \( x \) for experimental values in Table 1 using Eqs. (6) and (12). It can be seen from Fig. 8 that the concentration of NO decreases with increasing \( x \) and accordingly the removal efficiency of NO increases with increasing \( x \). When \( x \) is less than 0.4, the decreasing rate of NO concentration or the increasing rate of removal efficiency is comparatively fast; while when \( x \) is greater than 0.4, the concentration and removal efficiency of NO reach a steady level.

| Table 1 Parameter values used for solving the model equations. |
|-----------|----------------|----------------|----------------|----------------|
| Symbols   | Parameters                  | Formula                    | Values    | Units  | Reference |

| \( Y \)   | Yield coefficient of microorganisms | | | | |
7. Conclusion

In this paper, the system of nonlinear differential equations on nitric oxide removal in a biotrickling filter has been solved analytically. The model investigated the influence of parameters over the removal of NO from the oxygen in the BTF reactor under thermophilic conditions. Approximate analytical expressions pertaining to the concentration of NO in the gas phase and the biofilm phase for all values of the parameters are obtained using the Adomian decomposition method. Our results are compared with the numerical simulation and it gives satisfactory agreement. This analytical result helps us for the better understanding of the model.

Appendix A. Basic concepts of the Adomian decomposition method (ADM)

Consider the non-linear differential equation

\[
y'' + N(y) = g(x) \quad (A.1)
\]

with boundary conditions

\[
y(0) = A, \quad y'(b) = B \quad (A.2)
\]

where \( N(y) \) is a nonlinear function, \( g(x) \) is the given function and \( A, B, b \) are given constants. We propose the new differential operator, as below

\[
L = \frac{d^2}{dx^2} \quad (A.3)
\]

So, Eq. (A.1) can be written as

\[
L(y) = g(x) - N(y) \quad (A.4)
\]

The inverse operator \( L^{-1} \) is therefore considered as a twofold integral operator (Duan and Rach, 2011), as below

\[
L^{-1}(...) = \int_0^x \int_b^x (...) dx \, dx \quad (A.5)
\]

Applying the inverse operator \( L^{-1} \) on both sides of Eq. (A.4) yields

\[
y(x) = L^{-1}(g(x)) - L^{-1}(N(y)) + y'(b)(x - 0) + y(0) \quad (A.6)
\]

Using the boundary conditions Eq. (A.2), Eq. (A.6) becomes

\[
y(x) = L^{-1}(g(x)) - L^{-1}(N(y)) + Bx + A \quad (A.7)
\]

The Adomian decomposition method introduces the solution \( y(x) \) and the nonlinear function \( N(y) \) by infinite series

\[
y(x) = \sum_{n=0}^{\infty} y_n(x) \quad (A.8)
\]

and

\[
N(y) = \sum_{n=0}^{\infty} A_n \quad (A.9)
\]

where the components \( y_n(x) \) of the solution \( y(x) \) will be determined recurrently and the Adomian polynomials \( A_n \) of \( N(y) \) are evaluated using the formula

\[
A_n(x) = \frac{1}{n!} \frac{d^n}{dx^n} N \left( \sum_{k=0}^{\infty} \frac{y_k(x)}{k!} \right)_{x=0} \quad (A.10)
\]

which gives
Adomian decomposition method, Eq. (8) can be written in

\[ A_1 = N(y_0) \]
\[ A_1 = N'(y_0)y_1, \]
\[ A_2 = N'(y_0)y_2 + \frac{1}{2} N''(y_0)y_1^2, \]
\[ A_3 = N'(y_0)y_3 + N''(y_0)y_1y_2 + \frac{1}{4} N'''(y_0)y_1^3. \]  \hspace{1cm} (A.11)

By substituting Eqs. (A.8) and (A.9) in Eq. (A.7) gives

\[ \sum_{n=0}^{\infty} y_n = L^{-1}(g(x)) - L^{-1}\left(\sum_{n=0}^{\infty} A_n\right) + Bx + A \]  \hspace{1cm} (A.12)

Then equating the terms in the linear system of Eq. (A.11) gives the recurrent relation

\[ y_0 = L^{-1}(g(x)) + Bx + A, \quad y_{n+1} = -L^{-1}(A_n), \quad n \geq 0 \]  \hspace{1cm} (A.13)

which gives

\[ y_0 = L^{-1}(g(x)) + Bx + A, \]
\[ y_1 = -L^{-1}(A_0), \]
\[ y_2 = -L^{-1}(A_1), \]
\[ y_3 = -L^{-1}(A_2), \]  \hspace{1cm} (A.14)

From Eqs. (A.11) and (A.14), we can determine the components \( y_n(x) \), and hence the series solution of \( y_n(x) \) in Eq. (A.7) can be immediately obtained.

### Appendix B. Analytical solution of dimensionless NO concentration in the biofilm phase

The solutions of Eq. (7) and (8) allow us to predict the concentration profiles of NO in the gas phase and the biofilm phase. In order to solve Eq. (7), we have to solve Eq. (8) using the Adomian decomposition method. Eq. (8) can be written in the operator form,

\[ L(C_t) = x^2 N(C_t) \]  \hspace{1cm} (B.1)

where the differential operator \( L = \frac{d^2}{dx^2} \) and \( N(C_t) = \frac{C_t}{1 + \beta C_t} \).

Applying the inverse operator

\[ L^{-1}(\cdot) = \int_0^x \int_1^x (\cdot) dx'd\bar{x} \]  \hspace{1cm} (B.2)

on both sides of Eq. (B.1) yields

\[ \bar{C}_t(\bar{x}) = B\bar{x} + x^2 L^{-1}\left[ \frac{\bar{C}_t}{1 + \beta \bar{C}_t} \right] \]  \hspace{1cm} (B.3)

where \( B = \bar{C}_t(1) \) and \( A = \bar{C}_t(0) \). We let,

\[ \bar{C}_t(\bar{x}) = \sum_{n=0}^{\infty} \bar{C}_n(\bar{x}) \]  \hspace{1cm} (B.4)

\[ N[\bar{C}_t(x)] = \frac{\bar{C}_t}{1 + \beta \bar{C}_t} = \sum_{n=0}^{\infty} A_n \]  \hspace{1cm} (B.5)

In view of Eqs. (B.4) and (B.5), Eq. (B.3) gives

\[ \sum_{n=0}^{\infty} C_n(x) = B\bar{x} + A + x^2 L^{-1}\sum_{n=0}^{\infty} A_n \]  \hspace{1cm} (B.6)

We identify the zeroth component as

\[ \bar{C}_0(\bar{x}) = B\bar{x} + A \]  \hspace{1cm} (B.7)

and the remaining components as the recurrence relation

\[ C_{n+1}(x) = x^2 L^{-1}A_n, \quad n \geq 0 \]  \hspace{1cm} (B.8)

where \( A_n \) are the Adomian polynomials of \( \bar{C}_1, \bar{C}_2, \ldots \bar{C}_n \). We can find the first few \( A_n \) as follows:

\[ A_0 = N(C_h) = \frac{C_h}{1 + \beta C_h} \]  \hspace{1cm} (B.9)

\[ A_1 = \frac{d}{dx}[N(C_h + \lambda \bar{C}_h)]|_{\lambda=0} = \frac{\bar{C}_h}{(1 + \beta)^2} \]  \hspace{1cm} (B.10)

The remaining polynomials can be generated easily, and so,

\[ \bar{C}_1(\bar{x}) = 1 \]  \hspace{1cm} (B.11)

\[ \bar{C}_2(\bar{x}) = \frac{x^2(x - 2)}{2(1 + \beta)^2} \]  \hspace{1cm} (B.12)

\[ \bar{C}_3(\bar{x}) = \frac{x^2(x^2(x - 4) + 8)}{24(1 + \beta)^3} \]  \hspace{1cm} (B.13)

Adding (B.11), (B.12), (B.13), we get Eq. (13) in the text.
